PROJECT PROPOSED: eFoods App

This is a project I have proposed which allows the hotel managers to manage the menus in the restaurant. The app should allow the manager to update the menu, delete the menu, view available menus and update menus.

The app should contain the following pages/screens

Welcome screen.

Here the manager is welcomed with a warm welcome message which is attractive and appealing. This page should contain the buttons i.e. the button which allows the user to login if the user already has an account, clear message which guides the user if they do not have an account and a link which allows the user to create an account.

Signup page/screen

Here when the user clicks create account button from the welcome page, the user should be redirected to this page. Here is where the system captures the user's details like email, password. The system should also allow the user to confirm the password before storing the hash to the database to understand if the user can really remember the password. If the password does not match, the system should inform the user that passwords do not match. Then if passwords match, the user can click the create account button. Once the create account button is clicked, the system should store those credentials to the database. The user has to be redirected to the login page.

In case the user who already has an account clicked create account link mistakenly from the welcome page, there should be a clear message in the signup page saying already have account? Login. Then if the user clicks login button the user has to be redirected to the login page without creating an account again.

Login page

Once user clicks on login button from welcome page, the user is redirected to this page. In this page, the user has to enter the login credentials i.e. email, password. Once the user enters the credentials, user clicks login button then the system should be able to compare the input with that one stored in the database, if the credentials match, the user is redirected to the dashboard. If the credentials do not match, the system gives the user feedback that email address or password does not match depending on what is not matching.

For the case of users who have forgotten the password, the login page has the forgot password link so that the system should allow them to reset the password. Once user clicks forgot password link, the user should be redirected to the page for password reset.

Reset password page

Once the user clicks forgot password link from the login page, the user should be redirected here. In this page the user should be able to reset the password by entering the email address. If the email address exists, link is sent to email for resetting the password.

Dashboard page

Here immediately the user clicks login button from from the login page, the user is redirected to the dashboard. In the dashboard, the user should be able to perform many tasks such as

Add menu. The user can add menu to the system, once user clicks confirm the menu is stored to the database.

Delete menu. The system allows the user to delete menu also. Once the user clicks confirm delete the menu is deleted from the database

Update menu. If the user wants to update the menu, the system should allow the user to do such task

View menu. The system should also allow the user to view all the menus currently available in the restaurant in case the user wants to update, delete or add menu.

The colors I propose to use

Pure white. For background

Black; For text like password, email

Blue: For hints like enter email, the hint should be micheal72otim@gmail.com. This should guide the user on what to do.

Red: For delete menu icon

Green: For buttons like login, signup
